Comments:

Still early in the test and I think we will start to see animals gain in a compensatory manner moving forward. Egg counts dropped over the last 14 days which may have been a function of hot weather but might have also been due to the amount of sericea lespedeza within that grazing paddock. After the 28 day period is usually where we start to see animals fully acclimated to the environment so hopefully if your goat didn't fair well in this report it will next time. The gain or loss between weigh periods is always somewhat of a head scratcher? Remember gut fill could be an explanation at times and that is the reason we take 2 consecutive weights at the end of the test to minimize that element of potential bias. At this point we have 16 head out of 53 losing weight and every year I make the statement that if the test operates correctly we should see maybe 1 animal that doesn't perform well thus providing a good forage based test. If we feed animals too much feed then nutrition masks the genetic value.
